

# DSA 210 Project Proposal

This project aims to analyze the factors that influence tourism demand across countries, with a specific focus on whether tourists prioritize cost or safety when choosing travel destinations. The motivation behind this project comes from a simple but interesting question: when people decide where to travel, do they care more about affordability or how safe a destination is?

The data for this project will be collected from publicly available datasets on Kaggle. A tourism dataset containing international tourist arrivals by country will be used as the main variable. In addition, a cost of living dataset and a safety index dataset will be included to represent economic conditions and safety levels across countries. These additional datasets will be used to enrich the analysis and allow for a more meaningful comparison, as suggested in the project guidelines .

All datasets are country-based and will be combined using the country variable. The data mainly consists of numerical indicators such as number of tourists, cost of living index, and safety index. The datasets are expected to include data for many countries (around 50 or more), which should provide enough observations for analysis.

The data will be collected by downloading CSV files and processed in Python. After combining the datasets, some basic data cleaning and preparation steps will be applied. The project will then use data analysis and visualization techniques to explore the relationships between variables. Overall, the goal is to understand whether cost or safety plays a more significant role in attracting tourists and to interpret the findings accordingly.
